TaskVine / VineReduce / vine-cms-analysis-stack

Module 0 - Intro

3-hour hands-on tutorial for HEP graduate students

What we are running

- ADL benchmark Q6: a top-quark trijet selection on CMS Open Data
- Small, but the same shape as a real
- Written in coffea or RDataFrame; you pick one

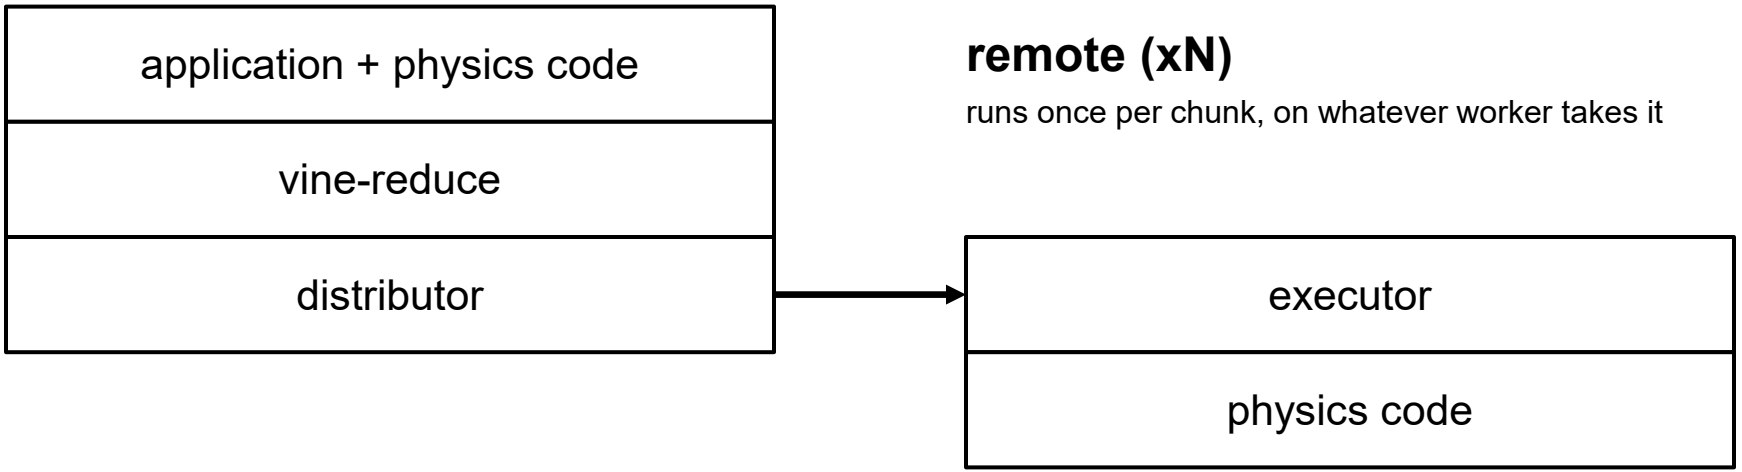

Partial results are added together until one result per dataset remains.

The shape of the stack

local (x1)

runs once, on the machine you are logged into

Why VineReduce, alongside coffea/RDataFrame

Parallelism

Owned by VineReduce

- Split a dataset into chunks
- Map the processor over chunks
- Reduce outputs back together

Distribution

Handed to a distributor (today: TaskVine)

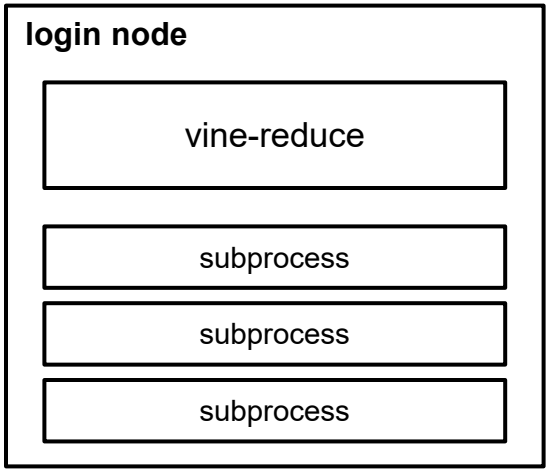

- Schedule chunks onto machines
- Transfer code and data
- Run on remote workers

The analysis code never changes. Only what it is handed to does.

Three places for execution

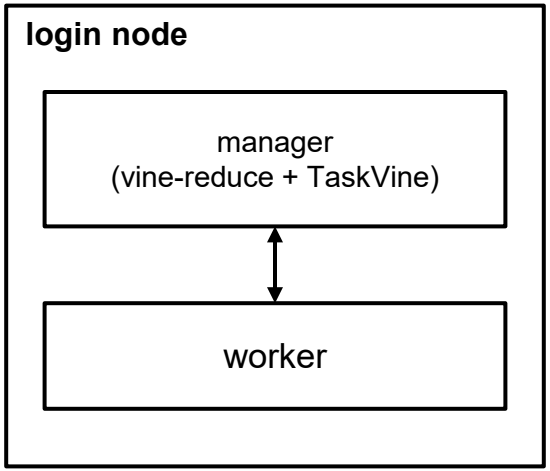

1 Local distributor

Module 2

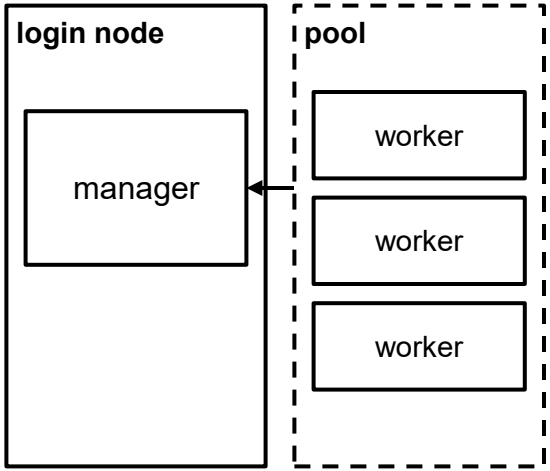

2 Local TaskVine

Module 3

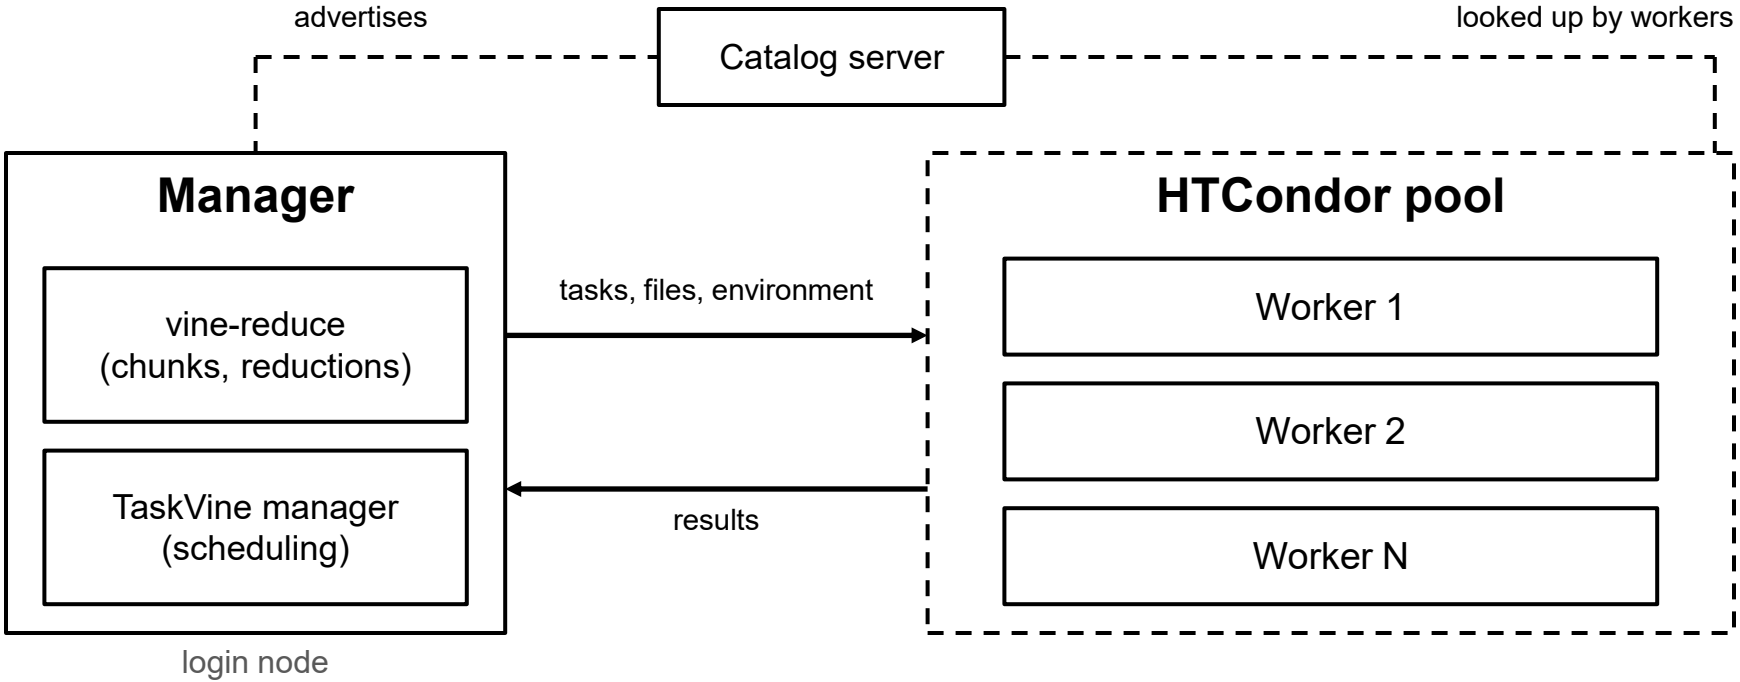

3 HTCondor pool

Module 4

The analysis code is the same in all three. Only what it is handed to changes.

Manager and workers

Workers find the manager through the catalog, connect to it, and read input data from storage (xrootd or a shared filesystem).

What the manager lets you control

Module 5	**Resources and chunk size**	What a task asks for, and how big it is
Module 6	**Checkpoints and restart**	Stop a run, resume without redoing work
Module 7	**result_postprocess**	Big outputs bypass the manager
Module 8	**Multiple processors**	Several analyses in one run
Module 9	**failure_proportion**	Keep going when some chunks fail
